

Claims with Quantitative Evidence

Claim	Page #	Evidence (Summary < 100 words)
The Project 0 Green robot's motion was characterized and quantified to calibrate autonomous behavior.	p. 4–5	Table 1 reports 6 metrics: average stride time = $4.214 \text{ s} \pm 0.05 \text{ s}$; stride length = $142.30 \pm 2 \text{ px}$; cadence = $14.2 \text{ steps min}^{-1}$ ($n \approx 40$ steps from timestamped logs with 1 Hz precision); average velocity = $25.54 \pm 0.3 \text{ px s}^{-1}$; total distance = 996.08 px ; total heading drift = 6.94° ($1.16^\circ \text{ step}^{-1}$). Positions were measured from AprilTag pixels via JSON logs with known sampling time.
The robot's heading drift caused deviation despite straight-line command.	p. 5 & Fig. 2	Drift quantified as 6.94° total over 996 px travel (0.7% angular error per cm). Data from $n \approx 40$ motion intervals; angle computed between consecutive tag positions.
The final bang-bang controller used calibrated thresholds for path following.	p. 6	Sensor values ranged 0–255; “on-path” ≥ 50 , difference > 30 triggered correction, and dead zone < 20 . Quantitative thresholds implemented directly in software with byte-precision inputs from the vision system.

Claims Without Quantitative Evidence

Claim	Page #	Comment on Evidence Gap
The Green robot showed “steady progress in control and accuracy.”	p. 7	No numerical trial-to-trial metrics or error rates reported.
“Movement appeared more stable and direct” in Trial 2.	p. 7	Qualitative; no measured angles or times given.
“Incremental improvement” and “better synchronization between sensor feedback and motion.”	p. 7	Descriptive only; no quantified heading error or response time.

“The Blue Team’s robot was the only one to complete the challenge autonomously.”	p. 8	No timing or position data provided to substantiate.
“Drift caused the Green robot to fall off the path.”	p. 8	Discussed mechanistically, not numerically verified beyond qualitative observation.
